# Purchases of cars and $\mathrm{CO}_{2}$ emissions 

by Marilena Locatelli, Ingeborg Rasmussen and Steinar Strøm

#### Abstract

A conditional logit model is estimated on Norwegian data for 2010. The data contains all purchases of cars for the period January to July. The estimates imply that taxes on $\mathrm{CO}_{2}$ emission have a negative impact on the choice of car and the model is used in simulations to demonstrate how purchases of cars can be shifted to types of car with lower emissions. We demonstrate that the total expected emission of $\mathrm{CO}_{2}$ is reduced when taxes on $\mathrm{CO}_{2}$ increases.

JEL: B21, Q58.
Keywords: purchases of cars, $\mathrm{CO}_{2}$ emission, microdata.

## 1 Introduction

The object of this paper is to investigate the choice of cars under different tax regimes on $\mathrm{CO}_{2}$ emissions and on other car characteristics. We have had access to all purchases of cars in Norway in the period January-July 2010. We have sorted all the purchases according to the potential emissions of $\mathrm{CO}_{2}$. These emissions stem from characteristics of the cars as well as from the use of fuel and how much the cars are used. The taxes are in part related to characteristics of the cars and on the use of fuel. We have assumed a standard driving length a year throughout the life of the car.

The reason for doing this study is that the Norwegian government likes to know whether and to what extent the different types of $\mathrm{CO}_{2}$ emission taxes affect the purchases of cars and if they can use the taxes to reduces substantially the emissions of $\mathrm{CO}_{2}$.

The paper is organized as follows. In the next Section, the models of the choice of car given the segment, and the choice of segment are explained. The data used in estimations are described in Section 3. The empirical specifications and estimation results are discussed in Section 4. In Section 5 we compare predictions and observed market shares while in Sections 6 we investigate some policy simulations, and changes of purchases of cars in and between car segments. Section 7 concludes. Some detailed tables upon the estimations and simulations are presented in Appendix A and $B$.

## 2 The model

We have divided the market into two markets: Big cars and smaller cars.
In the market for big cars we have three different segments of cars: sport cars, terrain cars and multiple cars. In each of these segments there is a varying number of types of cars.

In the market for smaller cars we have two segments: Small cars and medium cars.
In each segment the cars are sorted with respect to potential emission of $\mathrm{CO}_{2}$ measured in $\mathrm{g} / \mathrm{km}$. The range of $\mathrm{CO}_{2}$ interval is $2 \mathrm{~g} / \mathrm{km}$.

### 2.1 BIG cars

Within each segment the agent is assumed to choose a car that maximizes his or her utility. The choice categories, or alternatives, are the $\mathrm{CO}_{2}$ intervals. The utility function is assumed to be
random and extreme value distributed. The choice probabilities are thus conditional logit probabilities.

We do not observe characteristics of the buyers. The only characteristics that we observe are the characteristics of each car: Technical details like capacity (effect), cylinder volume, weight, fuel type, gear type and fuel consumption per km. Moreover we observe price, including all taxes, and the separate taxes. In Norway there are many taxes on cars. In what follows we have lumped together taxes attached to capacity, cylinder volume and weight and we denote the sum of these taxes simply as "Tax". In addition there is a tax related to the potential emission of $\mathrm{CO}_{2}$, which we denote " $\mathrm{CO}_{2}$ tax". Both "Tax" and " $\mathrm{CO}_{2}$ tax" vary across the $\mathrm{CO}_{2}$ intervals. The reason why "Tax" does this is that $\mathrm{CO}_{2}$ emissions are related to weight, cylinder volume and capacity. In the deterministic part of the random utility function these two tax variables, relative to the net price (net of taxes), are included. We expect that the higher these tax/price ratios are the less likely it is that cars with high potential emissions of $\mathrm{CO}_{2}$ will be chosen. In addition we also include "Fuel cost", which also contain tax on fuels. One component of this tax is a tax on $\mathrm{CO}_{2}$ emissions. In 2010 it was NOK 0.86 per liter gasoline (NOK 0.58 per liter diesel). We thus expect that the higher the fuel costs is the less likely it is that a car with a high potential emission of $\mathrm{CO}_{2}$ will be chosen.

Let subscript $i$ denote a car of type $i$ (that is, $\mathrm{CO}_{2}$ emission category $i$ ) and let $s$ denote the segment. Let $\mathrm{I}_{\mathrm{s}}$ denote the number of types of cars $\left(\mathrm{CO}_{2}\right.$ intervals) in segment s .

The conditional logit probabilities, given that segment $s$ is chosen, are given by

The agent chooses that segment that gives him (or her) the highest expected consumer surplus. The segment choice probabilities, denoted $\mathrm{P}_{\mathrm{s}}$, is then given by
(2) $\mathrm{P}_{\mathrm{s}}=\frac{\exp \left(\mathrm{Y}_{\mathrm{s}}+\alpha_{\mathrm{s}} \mathrm{Z}\right)}{\sum_{\mathrm{k}=1}^{3} \exp \left(\mathrm{Y}_{\mathrm{k}}+\alpha_{\mathrm{k}} \mathrm{Z}\right)} ; s=1, \ldots, 3$,
where
(3) $Y_{s}=\ln \sum_{j=1}^{I_{s}} \exp \left[b_{1 s} \frac{\text { Tax }_{j s}}{\text { Netprice }_{j s}}+b_{2 s} \frac{\mathrm{CO}_{2} \text { Tax }_{j s}}{\text { Netprice }_{j s}}+b_{3 s}\right.$ Fuelcost $\left._{j s}\right]$

Z is the change in the Oslo stock exchange during the considered period of 2010.

### 2.2 Small cars

The model is formally the same, with the exception that in this market we have specified two segments: Small cars and compact cars.

## 3 The data

The data used in this study come from "Opplysningsrådet for veitrafikk AS" (OFVAS), Norway and include $\mathrm{CO}_{2}$ emissions and different taxes on cars in Norway and consist of a sample of two different markets: Big and small cars.

In the following Table 1 we provide the description of the variables used in the estimation while the summary statistics are provided in Table 2 for big cars and in Table 3 for smaller cars.

Tax is measured in NOK as well as netprice. Thus the Tax/netprice is the ratio of tax to the netprice. The same also is the case for the $\mathrm{CO}_{2} \mathrm{Tax} /$ netprice. Note that the Tax could exceed the netprice. The change in the Oslo stock exchange was 9.05 percentage points during the considered period in 2010.

Table 1. Description of variables.

| Variables | Description |
| :--- | :--- |
| Segment | Discrete variable from 1 to 3 for big cars and from 1 to 2 for <br> small cars |
| category | $\mathrm{CO}_{2}$ emission $(\mathrm{g} / \mathrm{km})$. |
| pollution | dummy variable equal to 1 if car belongs to a certain $\mathrm{CO}_{2}$ <br> category, 0 otherwise |
| tax_netprice | $(\text { Tax })_{i s}$ <br> netprice $_{i s}$ |
| $\mathrm{CO}_{2}$ netprice | $\frac{\mathrm{CO}_{2} \mathrm{Tax}_{\text {is }}}{\text { netprice }_{\text {is }}}$ |
| fuelcost | Fuel cost in NOK per km |

In the market for big cars (Table 2), the segments are three, and the emissions (see the variable category) range from 134 to 388.

Table 2. Descriptive statistics - Market BIG cars

| Variable | Obs | Mean | Std. Dev. | Min | Max |
| :--- | :--- | :---: | :---: | ---: | ---: |
| category, $\mathrm{g} / \mathrm{km}$ | 599926 | 197.2722 | 44.49391 | 134 | 388 |
| pollution | 599926 | 0.022893 | 0.149562 | 0 | 1 |
| tax_netprice | 599926 | 1.037293 | 0.510917 | 0.442725 | 3.629107 |
| $\mathrm{CO}_{2}$ _netprice | 599926 | 0.443527 | 0.373151 | 0.049116 | 1.884805 |
| fuelcost | 599926 | 0.919655 | 0.264962 | 0.575148 | 2.124283 |

In the market small cars (Table 3) the variable category ranges from 86 to 208. The negative values of the variable $\mathrm{CO}_{2}$ netprice refer to a case in which drivers have a reimbursement for low emissions.

Table 3. Descriptive statistics - Market SMALL cars

| Variable | Obs | Mean | Std. Dev. | Min | Max |
| :--- | :--- | :--- | ---: | ---: | ---: |
| category | 2252477 | 149.1919 | 28.8885 | 86 | 208 |
| pollution | 2252477 | 0.0239297 | 0.1528301 | 0 | 1 |
| tax_netprice | 2252477 | 0.6400043 | 0.2344144 | 0.2612324 | 1.960286 |
| CO $_{2}$ _netprice | 2252477 | 0.1729871 | 0.1900422 | -0.1667797 | 0.8321599 |
| fuelcost | 2252477 | 0.7219793 | 0.1828173 | 0.3734172 | 1.122366 |

## 4 Estimates

In the following Subsections 4.1 we report the results of the maximum likelihood estimation of eq. (1), carried out with maximum likelihood conditional logit, respectively for big cars and for small cars. The coefficients have in general the expected signs and are significant.

### 4.1 Market BIG

In Table 4 we report the estimation of eq. (1) for segment 1,2 and 3.
Table 4. Estimate eq. (1) - market BIG

## a) segment 1 (sport cars)

| Number of obs | $=$ | 578 |  |  |
| :--- | :--- | :--- | :--- | :--- |
| LR chi2(3) | $=$ | 319.25 |  |  |
| Prob $>$ chi2 | $=$ | 0.0000 |  |  |
| Pseudo R2 | $=$ | 0.0790 |  |  |
| Log likelihood | $=-1861.3578$ |  |  |  |

| pollution | Coef. | Std. Err. | Z |
| :--- | ---: | ---: | ---: |
| $\mathrm{CO}_{2}$ netprice | -3.05071 | 0.151038 | -20.2 |
| fuelcost | -1.5748 | 0.144771 | -10.88 |

### 4.3 Elasticities in each segment and time

In order to evaluate the economic magnitude of the tax effects, we have calculated the direct demand elasticities according to the following equations.
(4) $E_{j 2 s}=b_{2 s}\left(1-\varphi_{j s}\right) \frac{\mathrm{CO}_{2} \text { Tax }_{j s}}{\text { Netprice }_{j s}}$
(5) $\mathrm{E}_{\mathrm{j} 3 \mathrm{~s}}=\mathrm{b}_{3 \mathrm{~s}}\left(1-\varphi_{\mathrm{js}}\right)$ fuelcost $\mathrm{j}_{\mathrm{js}}$
where:

- $\mathrm{E}_{\mathrm{j} 2 \mathrm{~s}}$ is the elasticity, for category $j$ and segment $s$, of the probability $\varphi_{\mathrm{js}}$ with respect to the variable tax_netprice $\left(\right.$ i.e. $\frac{\mathrm{CO}_{2} \mathrm{Tax}}{\text { Netprice }}$ ) and $\mathrm{b}_{2 \mathrm{~s}}$ is the estimated coefficient of eq. (1);
- $\mathrm{E}_{\mathrm{j} 3 \mathrm{~s}}$ is the elasticity, for category $j$, and segment $s$, of the probability $\varphi_{\mathrm{js}}$ with respect to the variable fuelcost (i.e. fuelcost NOK per km), and $b_{3 \mathrm{~s}}$ is the estimated coefficient of eq. (1).

In Table A1 of Appendix A, we include, for market big and for each category $j$, the estimated probabilities (phi_j_1_2010, phi_j_2_2010, phi_j_3_2010) and the elasticities e_j2_1, e_j3_1 for segment $1, e_{-} \mathrm{j} 2 \_2, e_{-} \mathrm{j} 3 \_2$ for segment 2 , and $\mathrm{e}_{\mathrm{J}} \mathrm{j} 2 \_3, \mathrm{e} \_\mathrm{j} 3 \_3$ for segment 3 .

The elasticity values have the correct signs and are increasing numerically with category $j$, that is with the emissions of $\mathrm{CO}_{2}$. Segment 3 (multiple cars) have in general higher elasticities numerically than segment 1 and 2.

In Table A2 we include the corresponding variables for market small. For segment 2 we have only computed e j3 2 since the variable tax_netprice has not been considered in the model.

## 5 Predictions and observed market shares

Figure 1 and Figure 2 compare observed and predicted market share respectively for the considered segments and for market BIG and market SMALL. We notice that the model predictions capture the overall trend, with the exception of some peaks that are present in the observed market shares.

Figure 1. Observed and predicted market share given the segment - Market BIG

Figure 2. Observed and predicted market share given the segment - Market SMALL

## 6 Policy simulations, changes in and between car segments

Using the estimates of eq. (1), we did some policy simulations to verify the changes in car choice probabilities in and among segments, both in market BIG and in market SMALL. In particular we want to show the impact on:
i - the probability of the choice of car given the segment ( $\varphi_{\text {ist }}$, Eq. 1 ),
ii - the probability of the choice of segment $\left(\mathrm{P}_{\mathrm{st}}\right.$, Eq.2-4),
iii - the global impact $\sum_{s} \sum_{i=1}^{I_{\text {st }}} \varphi_{\text {ist }} P_{\text {st }} u_{\text {ist }}$, where $\mathrm{u}_{\mathrm{ist}}$ is the average emission of $\mathrm{CO}_{2}$ in category $i$. when
a) doubling and tripling $\mathrm{CO}_{2}$ Tax values
b) increasing fuelcost per km by 20,40 and 60 percent

In the following Subsections 6.1, 6.2 and 6.3 we consider points i, ii, and iii for market big. The market small is considered in Subsections 6.4, 6.5, and 6.6.

### 6.1 Market BIG - changes in probability of the choice of car given the segment

In Tables B1, B2 and B3 of Appendix B, we report the impact of the policy simulations listed at point i , (cases a) and b)) for segment 1 (sport cars), 2 (terrain cars), and 3 (multiple cars), respectively. In general, for segment 1 and 2 , we observe that the probabilities for the very low emission categories increase, whereas the probabilities for higher emission categories decrease. This fact may be interpreted as a shift from high emission to low emission categories caused by an increase in tax on $\mathrm{CO}_{2}$ emissions. This effect is less evident in the case of fuelcost. Segment 4 appears more rigid to variations in taxes.

In the following Figure 3 and Figure 4, we report the impacts of the different simulations listed before.

Figure 3. Choice probability $\varphi_{\text {is }}$ of car by category given the segment: without any increase, doubling, and tripling $\mathrm{CO}_{2} \mathrm{Tax}$ (market BIG)

Figure 4 . Choice probability $\varphi_{\text {is }}$ of car by category given the segment: without any increase, with the increase of 20, 40 and 60 percent in fuelcost (market BIG)

### 6.2 Market BIG - changes among car segments

To investigate the impact on the choice of segments (point ii above) we calibrate eq. 2 so that the choice probabilities of segments fit the market shares of the segments.
To do that we have to compute the $\alpha$ 's so that $\mathrm{P}_{\text {st }}$ of eq. 2 is equal to the observed market share that is we have to solve the following system of three nonlinear equations:
(6) $\frac{\text { number of cars in segment } \mathrm{s}}{\text { all sold big cars }}=\frac{\exp \left(\mathrm{Y}_{\mathrm{s}}+\alpha_{\mathrm{s}} \mathrm{Z}\right)}{\sum_{\mathrm{k}=1}^{3} \exp \left(\mathrm{Y}_{\mathrm{k}}+\alpha_{\mathrm{k}} \mathrm{Z}\right)} ; \mathrm{s}=1,2,3$
with $\alpha_{3}=0$ and $Z=9.05$
The observed market share for sector BIG cars, are the following
segment 1, P_1_2010 $=0.0422$
segment 2, P_2_2010 $=0.8731$
segment 4, P_3_2010 $=0.0847$
Resorting to MATLAB to solve the above system, we find the following $\alpha$ 's:
$\alpha_{1}=-0.5717$
$\alpha_{2}=-0.3243$
This means that the stock exchange indicator favors multiple cars relative to sports car and terrain cars.

In Table 6 we include the impact on the choice probability of segment for the different simulation policies (point ii).

We observe that for segment 1 and 2 the probability decrease when doubling $\mathrm{CO}_{2} \operatorname{Tax}$ ( $\mathrm{P}_{-}$st_d) or tripling $\mathrm{CO}_{2} \mathrm{Tax}\left(\mathrm{P}_{\mathrm{s}} \mathrm{st} \mathrm{t}\right.$ ), while for segment 3 there is an increase. We observe a different trend when we increase fuelcost by 20,40 and 60 percent: by increasing fuelscost there is an increase in the probability for segments 1 and 2 , whereas we predict a decrease for segment 3 .

Table 6. Choice probability of segment: without any increase ( $\mathrm{P}_{-}$st), doubling $\mathrm{CO}_{2}$ tax ( $\mathrm{P}_{-}$st_d), tripling $\mathrm{CO}_{2}$ Tax ( $\mathrm{P}_{-}$st_t), increasing fuelcost by 20,40 and 60 percent (market BIG)

| Segment | $P_{-}$st | $P_{-}$st_d | $P_{-}$st_t | P_st <br> $+20 \%$ fuelcost | P-st <br> $+40 \%$ fuelcost | P_st <br> $+60 \%$ fuelcost |
| :---: | :---: | :---: | ---: | ---: | ---: | ---: |
| 1 | 0.0422 | 0.0322 | 0.0255 | 0.0503 | 0.0594 | 0.0696 |
| 2 | 0.8730 | 0.8666 | 0.8562 | 0.8860 | 0.8931 | 0.8952 |
| 3 | 0.0848 | 0.1011 | 0.1183 | 0.0637 | 0.0475 | 0.0353 |

### 6.3 Market BIG - global impact changes

The following Table 7 includes the total impact over segment 1, 2, and 3 of the different simulations (point iii) on total expected emission of $\mathrm{CO}_{2}$. We always predict a decrease when doubling $\mathrm{CO}_{2}$ tax (S_d), tripling $\mathrm{CO}_{2}$ avgift (S_t), or increasing fuelcost by 20 (S_20), 40 (S_40), and 60 percent (S_60).

Table 7. Expected total emission $\mathrm{S}=\sum_{s=1,2,4} \sum_{i=1}^{I_{s t}} \varphi_{i s t} P_{\mathrm{st}} u_{\text {ist }}$ doubling CO्O $\mathbf{C a x}$ (S_d), tripling $\mathrm{CO}_{2} \operatorname{tax}$ (S_t), increasing fuelcost by 20 (S_20), 40 (S_40), and 60 percent ( S_60) - (market BIG)

| market_BIG | S | S_d | S_t | S_20 <br> $(+20 \%$ fuelcost $)$ | S_40 <br> $(+40 \%$ fuelscost $)$ | S_60 <br> $(+60 \%$ fuelscostst $)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{CO}_{2} \mathrm{~g} / \mathrm{km}$ | 174.9802 | 171.2378 | 168.2488 | 174.0372 | 173.0199 | 171.96 |

### 6.4 Market SMALL - changes in probability of the choice of car given the segment

In Appendix B, Tables B4, and B5 we report the impact of the policy simulations listed at point i , (cases a) and b)) for segment 1 (small cars) and segment 2 (compact cars), respectively. As for market big cars, we observe that the probabilities, for the very low emission categories, increase when taxes are increased while for higher emission categories the probabilities go down.

Segment 1 appears more rigid to variations in taxes on fuel cost.
In the following Figure 5 and Figure 6, we report the impacts of the different simulations listed before for market big.

Figure 5 . Choice probability $\varphi_{i s}$ of car by category given the segment: without any increase, doubling, and tripling $\mathrm{CO}_{2}$ Tax (market SMALL)

Figure 6. Choice probability $\varphi_{\text {ist }}$ of car by category given the segment: without any increase, with the increase of 20, 40 and 60 percent in fuelcost (market SMALL)

### 6.5 Market small - changes among car segments

To investigate the impact on the choice of segments we have to compute the $\alpha$ 's so that $\mathrm{P}_{\mathrm{s}}$ of eq. 2 equals the observed market share, that is we have to solve a nonlinear equations similar to (eq. 6) above, which yields $\alpha_{1}=0.22$. Thus the stock exchange indicator favors small cars relative to compact cars.

Table 8 gives the impact on the segment probabilities of different simulation policy alternatives.
We observe that for segment 1 (small cars) the probabilities increase when doubling the $\mathrm{CO}_{2} \mathrm{Tax}$ ( $\mathrm{P} \_$st_d), tripling $\mathrm{CO}_{2} \operatorname{tax}\left(\mathrm{P}_{-} \mathrm{st} \mathrm{t}\right.$ ) or increasing fuelcost by 20,40 and 60 percent. The opposite happens for segment 2 (compact cars) the probabilities decrease. Thus there is a shift from compact cars towards small cars.

Table 8. Choice probability of segment: without any increase ( $\mathrm{P}_{-}$st), doubling $\mathrm{CO}_{2}$ Tax ( $\mathrm{P}_{-}$st_d), tripling $\mathrm{CO}_{2}$ Tax ( $\mathrm{P}_{-}$st_t), increasing fuelcost by 20,40 and 60 percent (market SMALL)

| Segment | P_st | P_st_d $_{-}$ | P_st_t $^{2}$ | P_st <br> $+20 \%$ fuelcost | P-st <br> $+40 \%$ fuelcost | P_st <br> $+60 \%$ fuelcost |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 0.33900 | 0.36956 | 0.37695 | 0.37670 | 0.41544 | 0.45477 |
| 2 | 0.66100 | 0.63044 | 0.62305 | 0.62330 | 0.58456 | 0.54523 |

### 6.6 Market SMALL - global impact changes

Table 9 reports the results of increasing taxes on the total expected emissions of $\mathrm{CO}_{2}$ in the market for small cars. We can observe that there is a decrease in the total expected emissions when doubling $\mathrm{CO}_{2} \mathrm{Tax}\left(\mathrm{S} \_\mathrm{d}\right)$, or tripling $\mathrm{CO}_{2} \mathrm{Tax}\left(\mathrm{S} \_\mathrm{t}\right.$ ), and there is a decrease also when increasing fuelcost by 20 (S_20), 40 (S_40), and 60 percent ( S_60).

Table 9. Expected total emission $\mathbf{S}=\sum_{s=1}^{2} \sum_{i=1}^{I_{s t}} \varphi_{\text {ist }} P_{\text {st }} u_{\text {ist }}$ doubling $\mathbf{C O}_{2}$ Tax (S_d), tripling $\mathrm{CO}_{2}$ Tax (S_t), increasing fuelcost by 20 (S_20), 40 (S_40), and 60 percent (S_60) - (market BIG)

| market_SMALL | S | S_d | S_t | S_-20 <br> $(+20 \%$ fuelcost $)$ | S_40 <br> $(+40 \%$ fuelcost $)$ | S_60 <br> $(+60 \%$ fuelcost $)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{CO}_{2} \mathrm{~g} / \mathrm{km}$ | 125.249 | 118.9588 | 114.9698 | 124.042 | 122.9217 | 121.8902 |

## 7 Conclusions

A conditional logit model is estimated on Norwegian data for 2010. The data contains all purchases of cars for the period January to July. The estimates imply that taxes on $\mathrm{CO}_{2}$ emission have a negative impact on the choice of car and the model is used in simulations to demonstrate how purchases of cars can be shifted to types of car with lower emissions. We demonstrate that the total expected emission of $\mathrm{CO}_{2}$ is reduced when taxes on $\mathrm{CO}_{2}$ increases.

## Appendix A
